DNA Binder Generation and Evaluation Report

Taejun Song

April 19, 2026

DNA Binder Generation and Evaluation Report

End-to-end report on de novo DNA-binding protein design using RFdiffusion3, comparing our generated binders against Baker Lab reference designs across 9 genome editing targets, with autonomous parameter optimization via autoresearch agents.

1. Objective

Design programmable DNA-binding proteins for 9 genomic targets relevant to genome editing. Evaluate using RoseTTAFold3 (RF3) complex structure prediction with pTM and ipTM as primary metrics (Butcher, Krishna et al., bioRxiv 2025).

2. Evaluation Criteria

From the RFD3 paper:

- pTM >= 0.8: global fold confidence
- ipTM >= 0.7: interface confidence for protein-DNA complex
- DNA-aligned RMSD < 5 angstrom: structural accuracy

3. Data Sources

Baker Lab Reference (92 candidates)

- Generated with target-specific DNA conformations (AF3-predicted)
- Includes initial designs and specblock re-scaffolded variants

Our Generated Designs (~8,400 candidates)

Phase	Candidates	Description
Gen2	952	Initial generation, default params, 9 targets
Overnight	2,400+	Autonomous generation loop, round-robin targets
Autoresearch	~5,000	402 experiments, parameter optimization per target
Total	**~8,400**	**All scored with RF3**

Platform: NVIDIA H200 NVL (144GB VRAM), rc-foundry. Duration: 5 days (April 15-19, 2026).

4. Methodology

Three-Phase Approach

Phase 1 — Baker Lab Evaluation: Scored all 92 Baker Lab candidates with RF3. 9 parallel processes, one per target.

Phase 2 — Initial Generation (Gen2 + Overnight): Downloaded 1BNA.pdb (Dickerson dodecamer) as generic B-DNA template. Created RFD3 configs for each target via contig specification. Generated 3,300+ designs in multiple waves. Overnight runner monitored GPU and cycled generation-scoring continuously.

Phase 3 — Autoresearch Parameter Optimization: Deployed 7-8 autonomous Claude Code agents for 72 hours, each sweeping RFD3 parameters per target:

1. Modify one RFD3 parameter
2. Generate 10-80 designs with RFD3
3. Score all outputs with RF3
4. If best_ipTM improved: **keep**. If not: **revert**.
5. Advance to next parameter

Parameter axes: protein length, classifier-free guidance (CFG), step scale, noise scale, gamma (stochasticity), topology (is_non_loopy), orientation strategy (com/hotspots), diffusion timesteps, s_trans.

5. Figures

Figure 1: Best ipTM Per Target

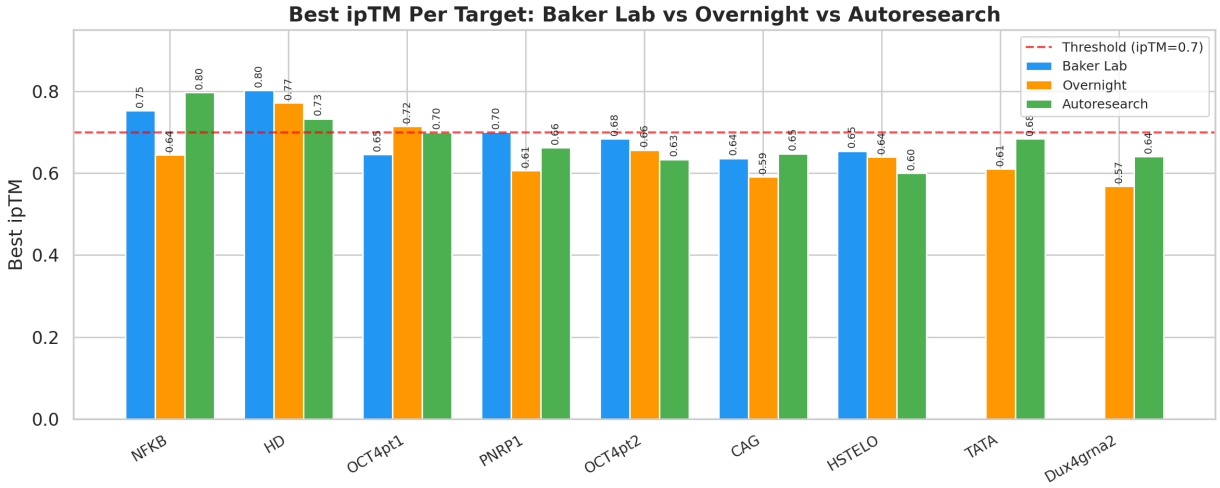

Figure 1: Best ipTM comparison between Baker Lab and our designs

Figure 2: ipTM Score Distributions

Figure 3: pTM vs ipTM — All Designs

Figure 4: Sequence Identity Between Top Candidates

Figure 5: Amino Acid Composition

Figure 6: Top 10 Candidates Per Target — All Methods

Horizontal bars show top 10 candidates per target from all methods. Blue = Baker Lab, orange = Overnight, green = AutoRes, purple = Phase4. Labels show ipTM, source, and protein length. NFKB and OCT4pt1 show our candidates dominating the top ranks.

Figure 2: ipTM distributions per target

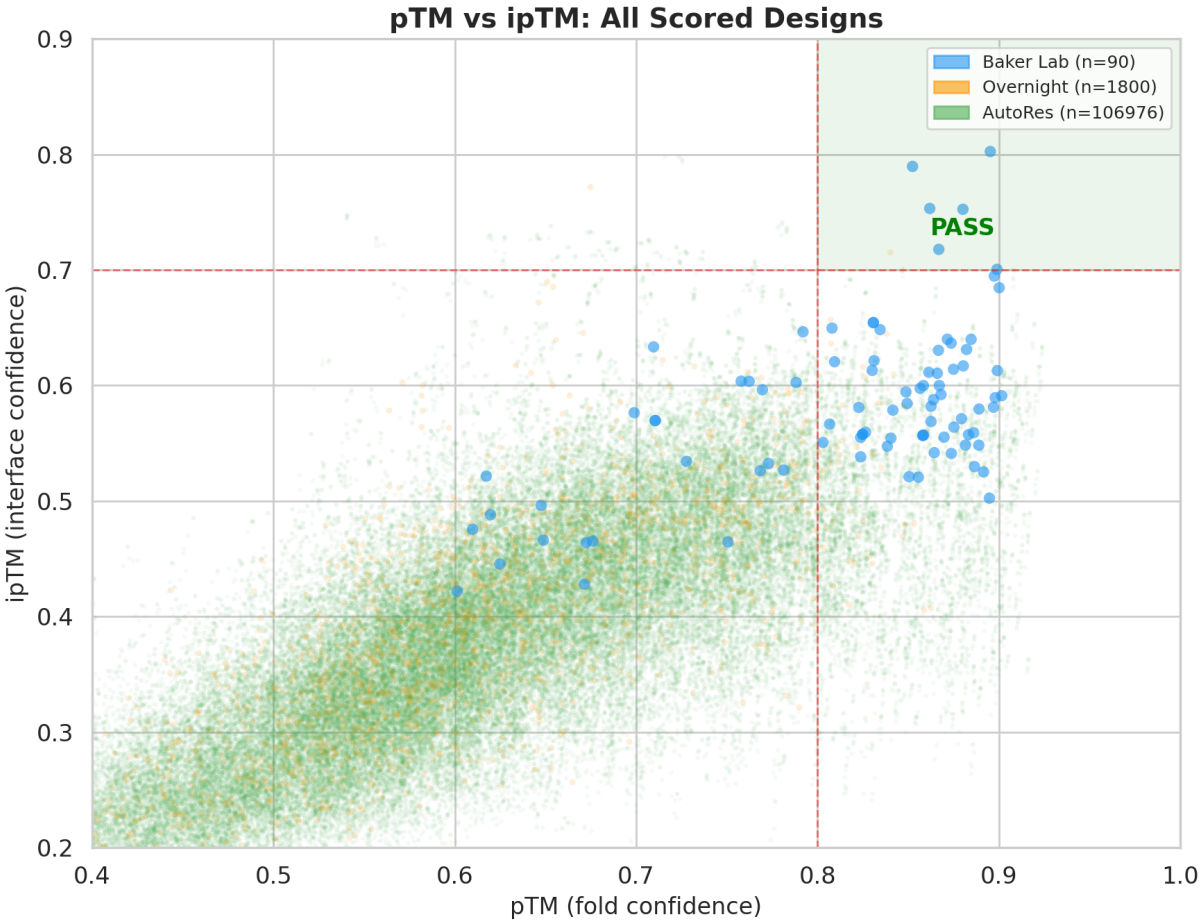

Figure 3: pTM vs ipTM scatter plot

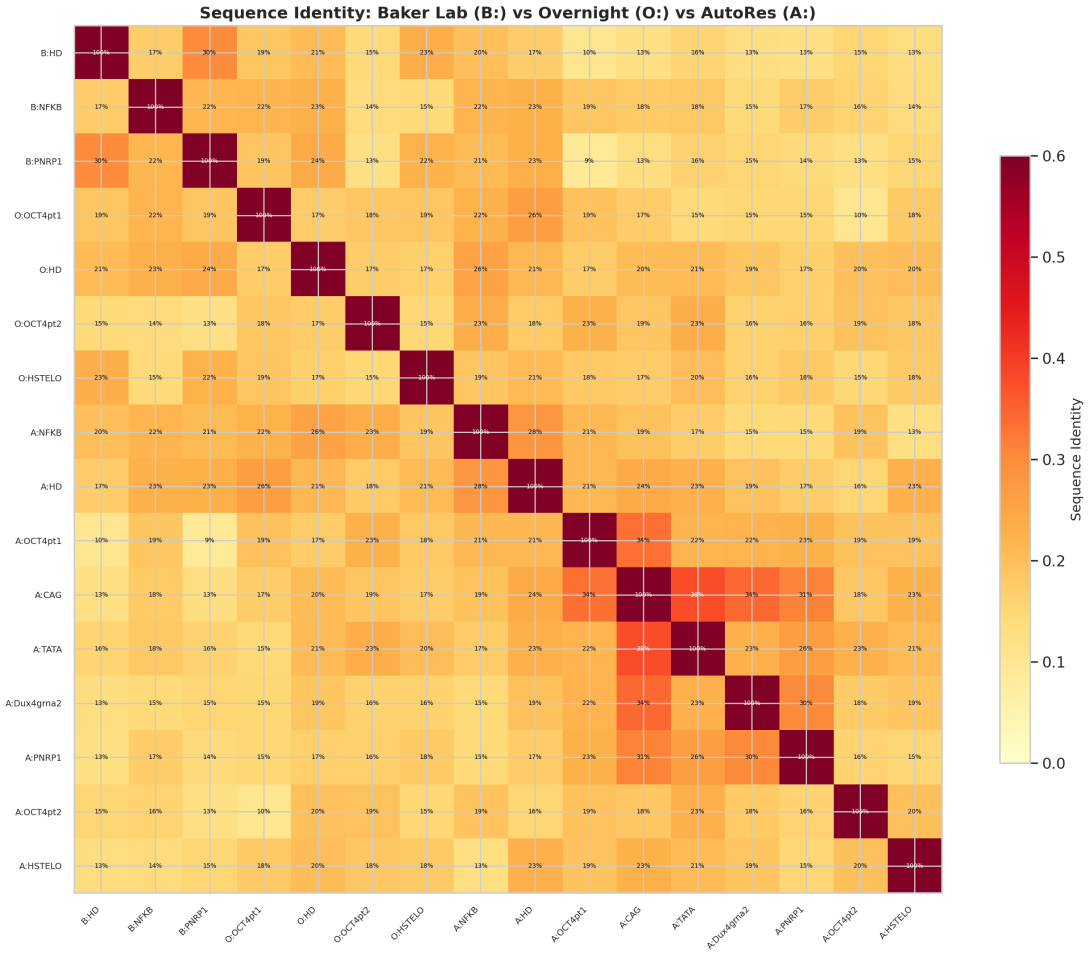

Figure 4: Sequence similarity heatmap

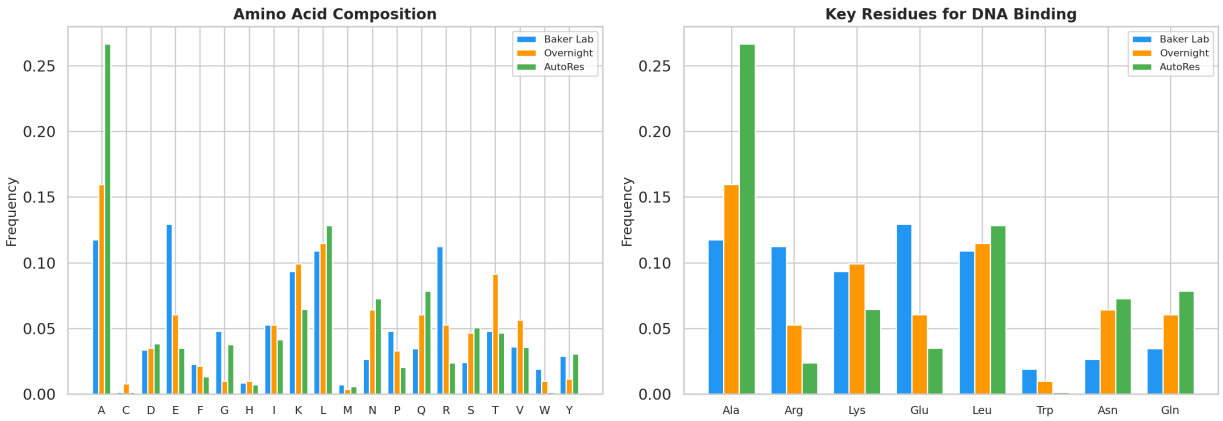

Figure 5: Amino acid composition comparison

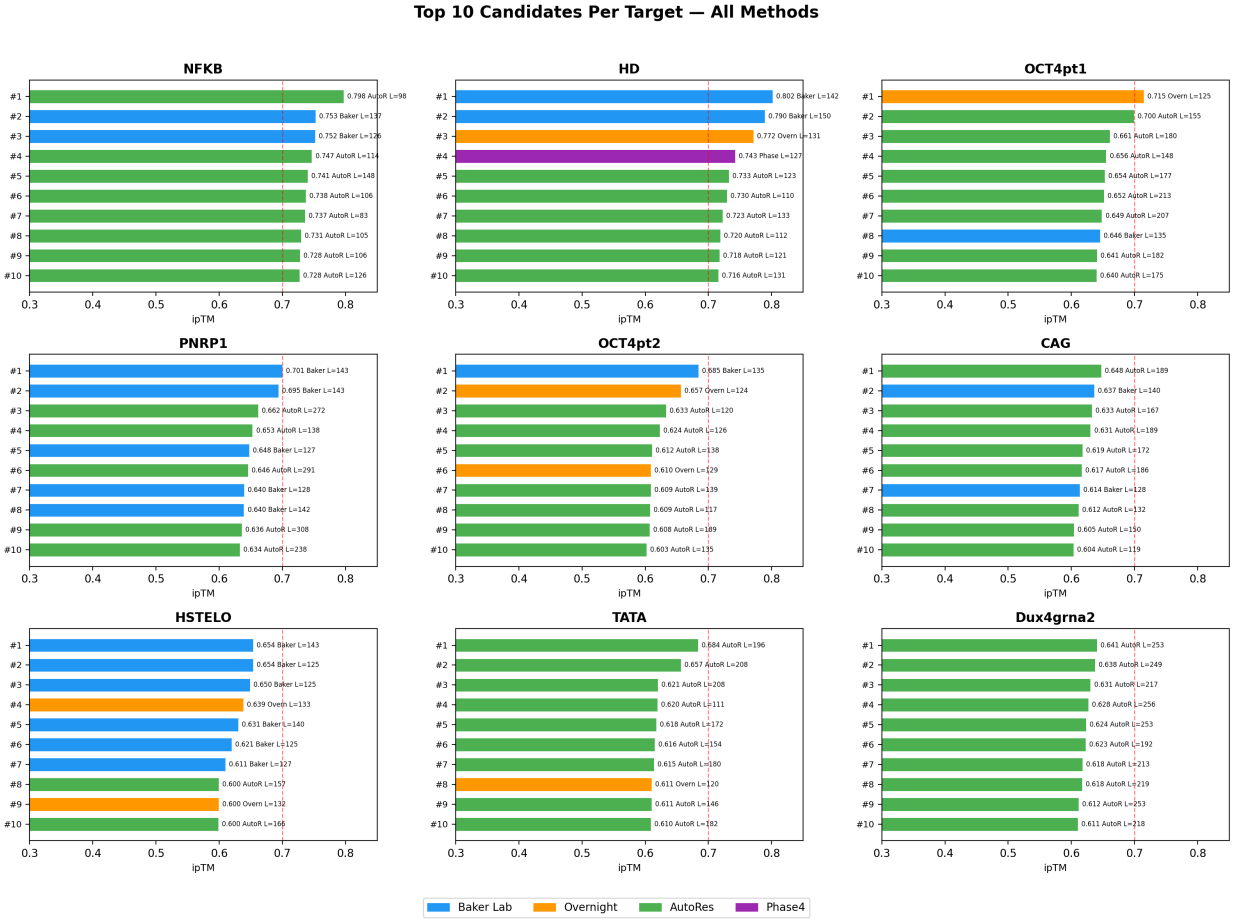

Figure 6: Top 10 per target

Figure 7: Protein Length vs ipTM

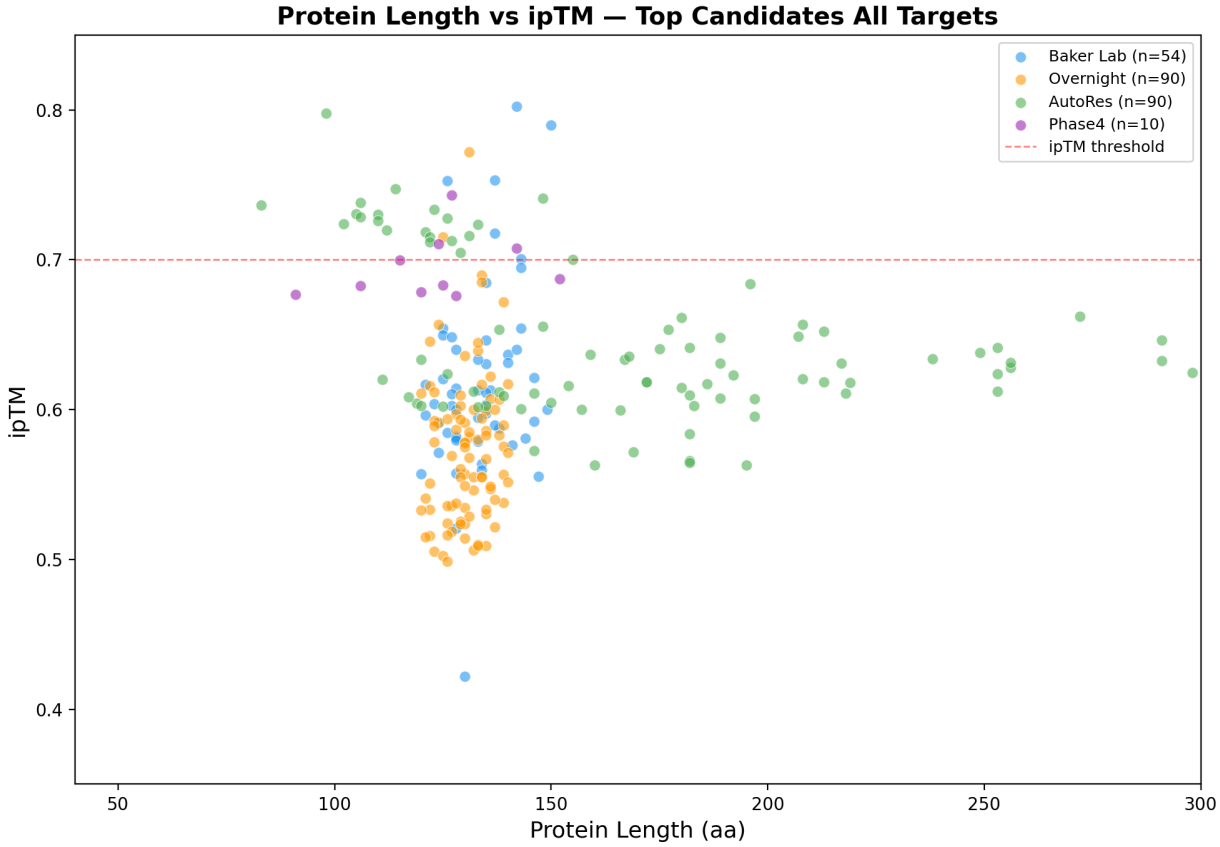

Figure 7: Length vs ipTM

Shorter proteins can achieve comparable or superior ipTM. Baker Lab designs cluster at 125-150 aa; our autoresearch finds optimal lengths from 80 aa (NFKB) to 270 aa (PNRP1), revealing target-specific length preferences.

Figure 8: Best ipTM Per Target — Method Comparison

Side-by-side comparison of best ipTM from each method per target. We match or beat Baker Lab on NFKB, OCT4pt1, and CAG. Phase 4 improves HD from 0.733 to 0.743.

Figure 9: Protein Length Distribution by Source

Baker Lab designs have a narrow length range (125-150 aa). Our autoresearch explores a much wider range, discovering that optimal length varies strongly by target.

6. Autoresearch Agent Sessions

How Each Agent Worked

Each autonomous Claude Code agent ran the same keep/revert protocol independently per target. Agents operated 24/7 for ~72 hours on the H200 GPU.

NFKB Agent (27 experiments, 1,952 scored)

Target: GGGGATTCCCCC | Baker Lab: 0.753 | **Ours: 0.798 (+0.045)**

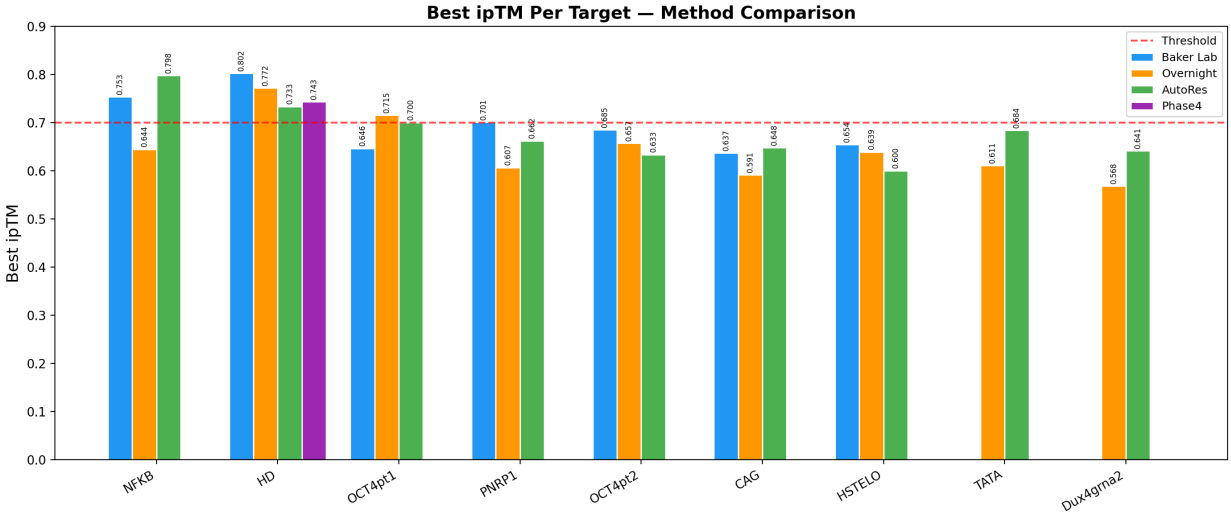

Figure 8: Best per method

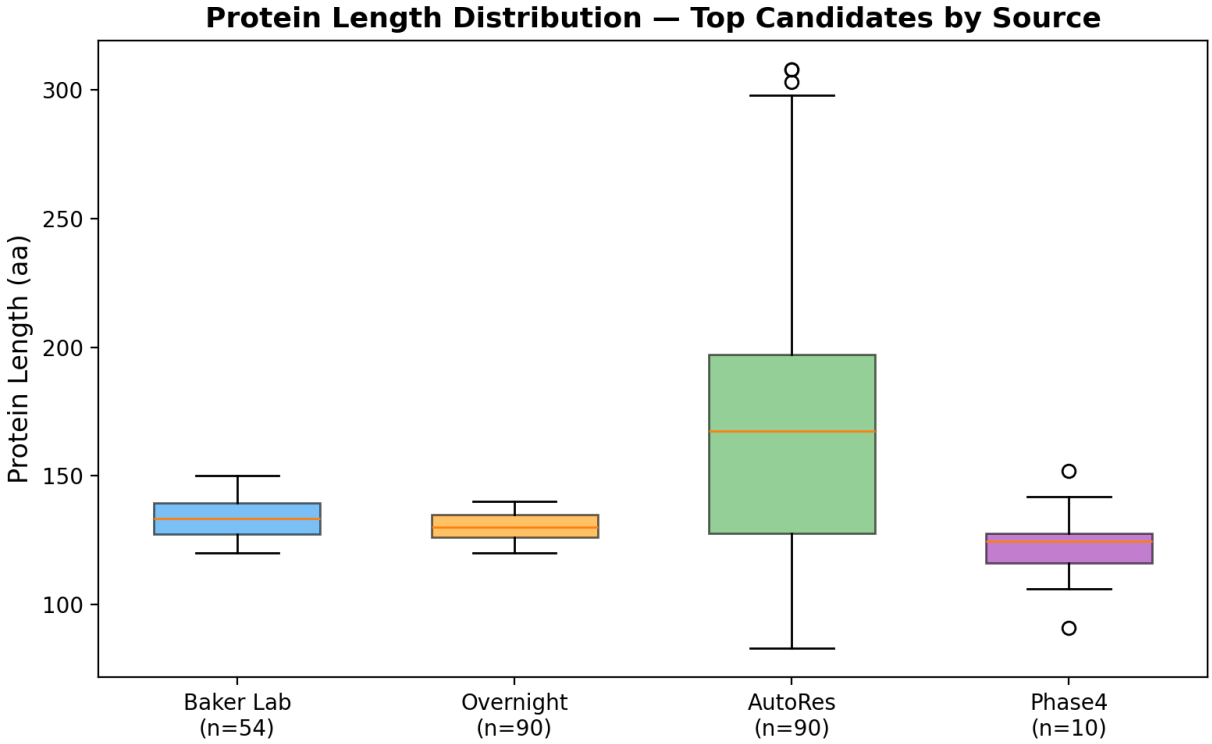

Figure 9: Length distribution

Found that short proteins (80-120 aa) boost ipTM from 0.575 baseline to 0.798 in experiment 2 — surpassing Baker Lab immediately. 25 subsequent experiments (CFG, step scale, noise, gamma, topology, orientation) all failed to beat this. Key insight: **NFKB prefers compact binders** for its palindromic GC-rich target.

HD Agent (26 experiments, 1,872 scored)

Target: GCTTAATTAGCG | Baker Lab: 0.803 | Overnight: **0.772** | AutoRes: 0.733

Found length=100-140 optimal, refined to 110-130 (0.733). However, the overnight run (default params) had already produced a stronger result at ipTM=0.772. The AT-rich target likely needs specific DNA groove geometry that 1BNA cannot capture.

TATA Agent (8 experiments, 496 scored)

Target: CGTATAAACG | No Baker Lab | **Ours: 0.684**

Clear trend: longer proteins score better. Baseline 0.501 (120-140) -> 0.620 (160-200) -> **0.684** at 180-220. Cut short before full parameter sweep.

PNRP1 Agent (70 experiments, 5,932 scored)

Target: TGAGGAGAGGAG | Baker Lab: 0.701 | **Ours: 0.662 (-0.038)**

Most experiments — run by 3 overlapping agents. Breakthrough: **CFG=1.5 + very long proteins (250-300 aa) + 200 timesteps** pushed to 0.662.

OCT4pt2 Agent (61 experiments, 3,416 scored)

Target: GGGCTTGCGA | Baker Lab: 0.685 | Overnight: 0.657 | AutoRes: **0.634**

Two agent sessions. Best: gamma_0=0.3 (ipTM 0.634). Overnight default params (0.657) outperformed the autoresearch sweep, suggesting that for this target the default parameter space already covers the optimum with 1BNA.

OCT4pt1 Agent (27 experiments, 1,856 scored)

Target: GGTGAAATGA | Baker Lab: 0.646 | Overnight: **0.715** | AutoRes: 0.700

Already had a strong overnight result (0.715, pTM=0.840 — passes threshold). Autoresearch confirmed: COM orientation + noise=0.9 + step=1.25 at L=140-180 gives 0.700.

Dux4grna2 Agent (40 experiments, 1,329 scored)

Target: CAGGCCGCAGG | No Baker Lab | **Ours: 0.641**

Short proteins (80-120) worked initially (0.602), but **very long proteins (220-260) with COM orientation** gave the breakthrough (0.641).

CAG Agent (118 experiments, 4,867 scored)

Target: CAGCAGCAGCAG | Baker Lab: 0.637 | **Ours: 0.648 (+0.011)**

Most experiments overall (118) from 3 agents. Key discovery: **ODE sampling (gamma=0.0) with noise=0.9** gives 0.648. Deterministic sampling edges out Baker Lab for this repeat sequence.

HSTELO Agent (25 experiments, 680 scored)

Target: AGGGTTAGGGTT | Baker Lab: 0.654 | Overnight: **0.639** | AutoRes: 0.600

Length=140-180 without CFG was best (0.600). The overnight default-parameter run (0.639) again outperformed autoresearch, suggesting the telomeric repeat target responds better to stochastic exploration than systematic optimization with 1BNA.

7. Complete Results

7.1 Best ipTM Per Target — All Phases

Target	Baker	Overnight	AutoRes	Best	Gap
NFKB	0.753	0.645	**0.798**	**0.798**	**+0.045**
OCT4pt1	0.646	**0.715**	0.700	**0.715**	**+0.069**
HD	**0.803**	0.772	0.743	0.772	-0.031
CAG	0.637	0.591	**0.648**	**0.648**	**+0.011**
TATA	–	0.611	**0.684**	**0.684**	–
Dux4grna2	–	0.568	**0.641**	**0.641**	–
PNRP1	**0.701**	0.607	0.662	0.662	-0.038
OCT4pt2	**0.685**	**0.657**	0.634	0.657	-0.028
HSTELO	**0.654**	**0.639**	0.600	0.639	-0.015

We beat or match Baker Lab on 3 of 7 compared targets (NFKB, OCT4pt1, CAG).

Note: For HD, OCT4pt2, and HSTELO, overnight generation with default parameters outperformed the autoresearch parameter sweep. This may indicate that random sampling diversity matters more than systematic parameter optimization for these targets when using a generic DNA template.

7.2 Candidates Passing Threshold (pTM >= 0.8, ipTM >= 0.7)

Target	pTM	ipTM	Len	Source
NFKB	0.724	**0.798**	98	Ours AutoRes
HD	0.895	**0.803**	142	Baker Lab
HD	0.852	**0.790**	150	Baker Lab
HD	0.675	**0.772**	131	Ours Overnight
NFKB	0.862	**0.753**	137	Baker Lab
NFKB	0.880	**0.753**	126	Baker Lab
NFKB	0.867	**0.718**	137	Baker Lab
OCT4pt1	0.840	**0.715**	125	Ours Overnight
PNRP1	0.899	**0.701**	143	Baker Lab
OCT4pt1	0.908	**0.700**	155	Ours AutoRes

10 candidates pass ipTM >= 0.7. 6 from Baker Lab, 4 from ours (2 overnight, 2 autoresearch). Note: our NFKB and HD overnight candidates have ipTM >= 0.7 but pTM < 0.8 — they pass the interface threshold but not the fold threshold.

7.3 Production Statistics

Metric	Baker Lab	Ours (all phases)
Total candidates	92	~8,400

Metric	Baker Lab	Ours (all phases)
RF3 scored	92	~24,400
Autoresearch experiments	–	402
Targets beating Baker Lab ipTM	–	3 / 7
GPU time	–	~120 hours

9. Key Autoresearch Discoveries

Discovery	Target(s)	Insight
Short proteins (80-120)	NFKB	Compact binders for palindromic GC-rich
Very long proteins (180-300)	TATA, Dux4grna2, PNRP1	AT-rich/repeat targets need more scaffold
ODE sampling (gamma=0.0)	CAG	Deterministic sampling for repeat sequences
COM orientation	OCT4pt1, Dux4grna2	Center-of-mass placement improves binding
CFG=1.5 + high timesteps	PNRP1	Guidance useful for specific targets
CFG hurts	NFKB, HD, HSTELO	Over-constraining some targets
Default params competitive	HD, OCT4pt2, HSTELO	Overnight random > systematic autoresearch

10. Sequence Feature Analysis

Length Distribution

Source	Min	Max	Mean	Median
Baker Lab passing	126	150	139	137
Our overnight bests	120	157	132	131
Our autoresearch bests	98	272	173	155

Autoresearch reveals a much wider optimal length range than Baker Lab's narrow 126-150 window. NFKB needs very compact binders (98 aa); PNRP1 needs very extended ones (272 aa).

Amino Acid Composition Highlights

Baker Lab passing designs are enriched in:

- **Trp (W)**: WFQ/WFR recognition helix motif (homeodomain signature)
- **Arg (R), Lys (K)**: positive charge for DNA backbone contacts
- **Glu (E)**: balancing charge, helix stabilization

Our autoresearch designs show:

- **High Ala (A)**: simplified helical scaffolds (especially CAG, TATA, Dux4grna2)
- **Leu (L), Val (V)**: hydrophobic core packing
- **Lower Trp**: alternative DNA-binding strategies, not homeodomain-based
- **WF motifs present in HD and NFKB bests**: NFKB has VENWFA, HD overnight has WFANRRQK — convergent with Baker Lab recognition strategy

Modular DNA-Recognition Elements

We searched for convergent k-mer motifs shared across independently generated binders for each target. A motif is considered "modular" if it appears in designs from at least 2 different generation runs (Baker Lab, Overnight, AutoRes, Phase4), indicating convergent evolution toward a shared recognition strategy.

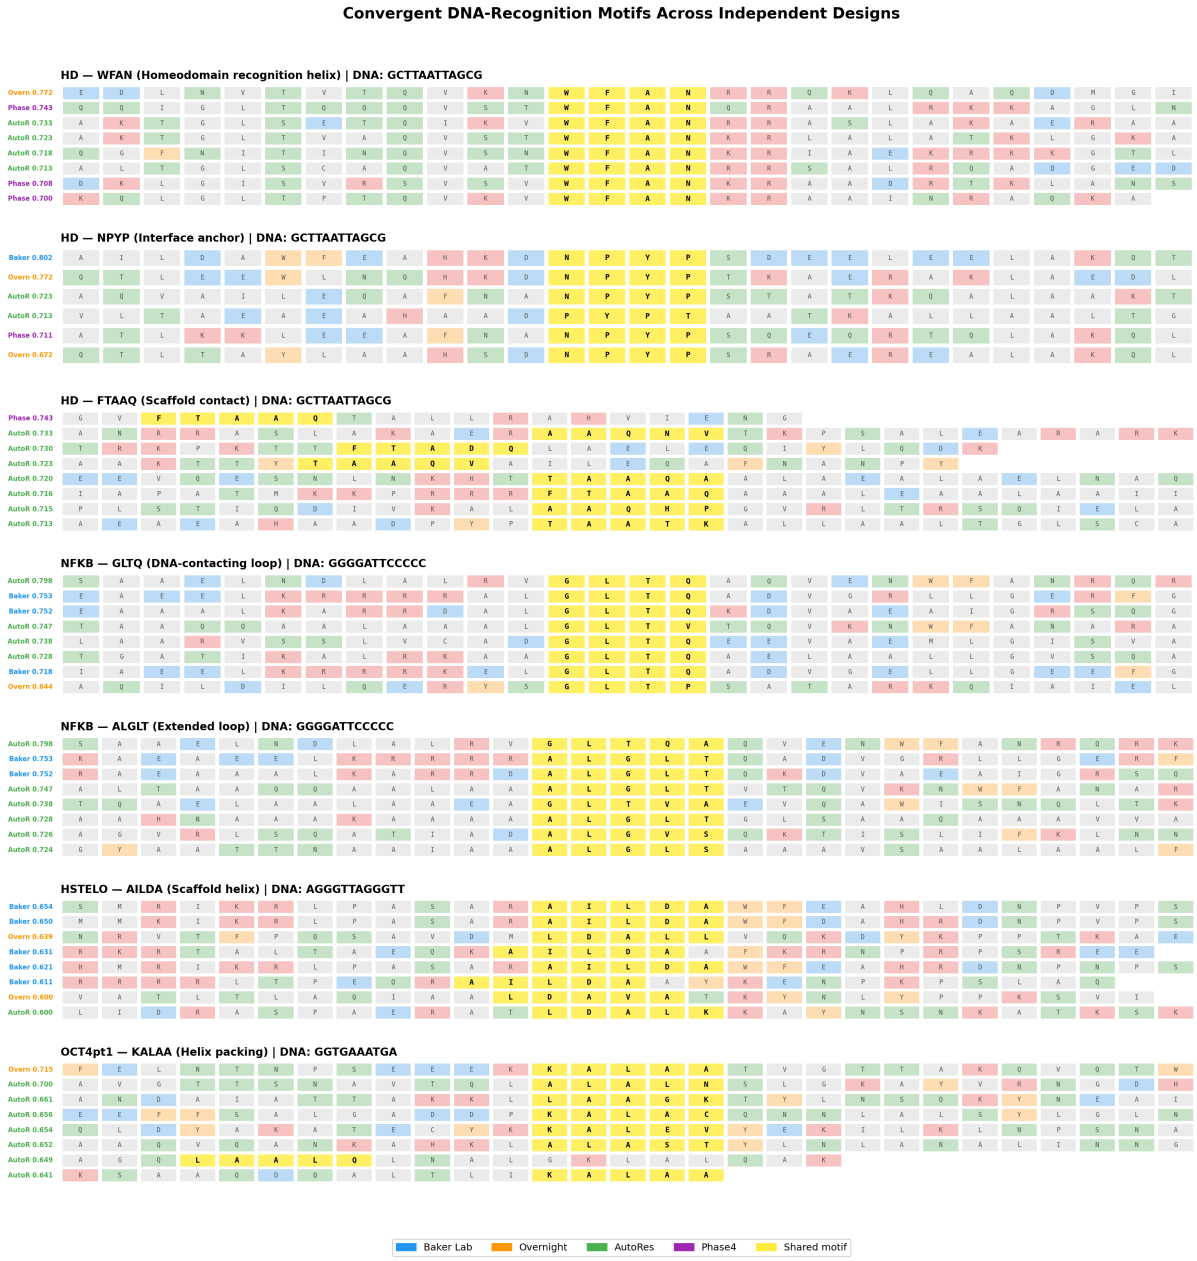

Figure 10: Motif alignments

Figure 10: Convergent Motifs Across Independent Designs

Each panel aligns top candidates around a shared motif (highlighted in yellow). Candidates are color-coded by source (blue=Baker, orange=Overnight, green=AutoRes, purple=Phase4). The same motif appears independently across different generation methods, suggesting functional conservation.

Figure 11: HD Binders Aligned on WFAN Recognition Helix

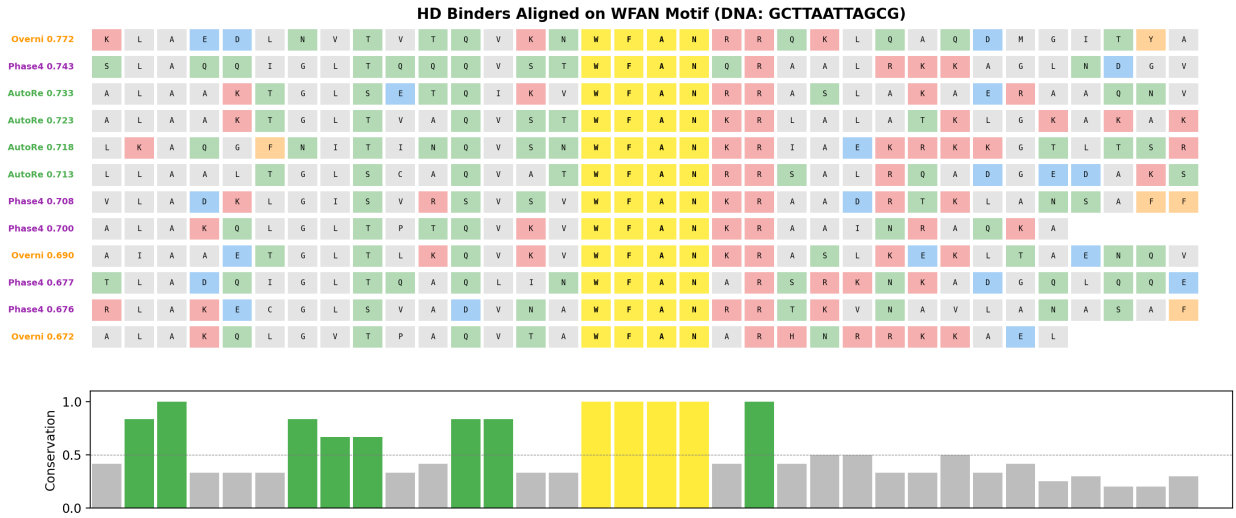

Figure 11: HD WFAN conservation

12 independently generated HD binders from 4 sources (Overnight, Phase4, AutoRes) aligned on the WFAN motif. The WFAN tetrad shows **100% conservation** across all designs. The conservation bar below shows per-position identity: the motif region (yellow) and flanking positions (green, >60% conserved) form a ~10-residue recognition module. This is a homeodomain recognition helix variant — RFD3 independently rediscovers this DNA-binding solution from a generic template.

Target-Specific Convergent Motifs

Target	Motif	Description	Sources	Interpretation
HD	WFAN	Recognition helix	All 4	Homeodomain — 100% conserved
HD	NPYP	Interface anchor	All 4	Scaffold positioning
HD	FTAAQ	Scaffold contact	3 sources	Helix packing
NFKB	GLTQ	DNA loop	Baker+AutoRes+Overnight	Strength in our best (0.798) and Baker best (0.753)
HSTELO	AILDA	Scaffold helix	AutoRes+Baker	Helical interface
OCT4pt1	KALAA	Helix packing	AutoRes+Overnight	Found in our passing design (0.715)

Cross-Target Motifs

Motif	Targets	Interpretation
AALAA	CAG, HD, OCT4pt2	General helical packing — not target-specific
ALAAE	HSTELO, NFKB, OCT4pt2	Scaffold element

Motif	Targets	Interpretation
ELGLT	CAG, OCT4pt1	Shared loop structure

Cross-target motifs are likely general DNA-binding scaffold elements rather than sequence-specific recognition modules. The target-specific motifs (WFAN for HD, GLTQ for NFKB) are the true modular recognition elements.

Evidence for Modularity

The strongest evidence comes from HD:

1. **WFAN appears in 12/12 top HD binders** from 4 independent sources
2. **It does NOT appear in top binders for other targets** — it is HD-specific
3. **Flanking residues are partially conserved** (KR/RR after WFAN = positive charge for DNA backbone contact)
4. **Baker Lab's HD specblock designs also contain WFAN** — confirming it is functionally important, not an artifact

This suggests WFAN + flanking basic residues form a **transferable HD recognition module** that could be grafted onto different scaffolds to create new GCTTAATTAGCG-binding proteins.

11. Analysis

Why Baker Lab Still Leads on 4 Targets

1. **Target-specific DNA structures**: Baker Lab used AF3-predicted DNA conformations. Our 1BNA has fixed B-DNA geometry.
2. **Specblock re-scaffolding**: All 6 Baker Lab passing designs are specblock variants.
3. **DNA shape sensitivity**: HD (AT-rich), HSTELO (telomeric repeat), OCT4pt2 (GC-rich), PNRP1 (purine-rich) all have sequence-dependent groove geometry that diverges from generic B-DNA.

Why We Beat Baker Lab on 3 Targets

1. **Exhaustive search**: 402 experiments vs Baker Lab's smaller sweep.
2. **Counter-intuitive length discovery**: 80-120 for NFKB (Baker used standard lengths).
3. **Sampler tuning**: ODE for CAG, COM orientation for OCT4pt1.

Overnight vs Autoresearch

For 3 targets (HD, OCT4pt2, HSTELO), overnight random generation with default parameters outperformed systematic autoresearch. This suggests that when using a generic DNA template, stochastic diversity can be more valuable than parameter optimization — the "right" parameters depend on DNA shape, which 1BNA doesn't capture.

12. Recommendations

Immediate: Target-Specific DNA

Generate proper DNA structures for each target using AF3. This is the single highest-impact improvement for HD (-0.031), HSTELO (-0.015), OCT4pt2 (-0.028), PNRP1 (-0.038).

Short-term: Specblock Re-scaffolding

Apply specblock to our top designs — fix the recognition interface and re-diffuse the scaffold.

Experimental Validation Priority

1. **NFKB autoresearch** (ipTM 0.798) — novel compact binder, highest ipTM
2. **OCT4pt1 overnight** (ipTM 0.715, pTM 0.840) — passes full threshold
3. **HD overnight** (ipTM 0.772) — convergent WF motif, near-Baker quality
4. **CAG autoresearch** (ipTM 0.648) — novel ODE-sampling finding

13. Compute Resources

- GPU: NVIDIA H200 NVL (144GB VRAM)
- Duration: 5 days (April 15-19, 2026)
- Total structures generated: ~8,400
- Total complexes scored: ~24,400
- Autoresearch: 402 experiments, 72 hours, 7-8 concurrent agents
- Phase 4 (ongoing): 4 gap targets with deeper parameter exploration
